

WONDER DAILY

The light we cannot see.

Make a little book

1 Fold it into 8 boxes. Open it flat.

2 Fold short end to short end. Cut the thick line. Open it.

3 Fold the long way, pictures out. Push the ends in.

4 Fold into a book. Page 1 goes on the front!

Keep the clue

The museum lamp switches off. The green fluorescence stops almost at once. Little sketches a lamp, a star, and light coming out.

Light in, light out

The green star has a special coating: a fluorescent phosphor. It absorbs UV-A and quickly emits green light.

Two paper stars

A green star shines in a quiet museum case. Beside it, a cream star stays dull. Both sit under the same dark-looking lamp.

Beyond violet

Their search begins long ago. In 1801, Johann Ritter spread sunlight into a rainbow.

A name for the glow

Another display tells of George Stokes. In 1852, he studied materials that took in light and gave out a different color.

A dark-looking light

Back at the stars, Little studies the black light. It gives out mostly UV-A, the ultraviolet near visible violet. Our eyes cannot see UV-A.
