

From deep dark to daylight

A diamond's story. · Curiosity-led family day

Name _____

Date _____

Little Wonderer peers at the deep rock. "No sunshine down there!" Long ago, far below the ground, heat and enormous pressure helped carbon grow into a diamond crystal. Its beginning took a long time.

At the next table, a model towers over the stone. Its balls stand for tiny carbon atoms. "Neighbors!" says Little Wonderer. Strong connections hold them in a repeating pattern. A diamond keeps that pattern inside.

"Then how did it get up here?" Little Wonderer follows an arrow. Long after diamonds formed, some volcanic eruptions carried them upward in rising rock. Big Wonderer traces the path beside Little's finger.

The next label says 10. Diamond sits at the top of the Mohs scratch scale. "Nothing can hurt it?" Little asks. "It can still chip," says Big Wonderer. Hard to scratch does not mean impossible to break.

A lamp shines on the cut-diamond model. Light bends as it enters, bounces inside, and comes out again. The flat, cut faces guide its path. Little Wonderer follows the orange line. "The light came from somewhere else!"

Little shifts sideways. One face dims; another catches the light. Together, they sketch two places to look from. "What if the light moved?" Little asks. Big Wonderer leaves room for the question.

Talk together: Why did Little change the idea that nothing could hurt a diamond? Where did the light in the model's bright path begin?
